

Problem Statement

TaskFlow Product Health Monitor — 05-elevenlabs-producthealth

The Problem / Opportunity

TaskFlow's product-health signals user feedback, support tickets, and product metrics; live in three separate systems of record, each owned by a different team. A PM or TPM who wants a quick answer about product health today has to know which dashboard or team owns that particular data, then go find someone available to pull it. There is no single place to ask.

This project sits inside a broader assignment: build a multi-agent voice AI system using ElevenLabs that lets a PM query all of this product-health data simply by asking questions out loud. The system needs to use workflow orchestration: not a single do-everything prompt; to route each question to the specialist best equipped to answer it, and to keep each specialist's knowledge cleanly scoped to its own domain.

Who's Affected

Product managers and TPMs who need fast, accurate, cross-domain answers about product health; without personally hunting through three different dashboards, and without waiting on whichever team currently owns that data to be available to answer.

Workflow Elements

Any solution to this problem needs the following building blocks:

- Intent classification / routing: reliably understanding what a caller is asking about and directing them to the right resource — without answering prematurely or guessing.
- Domain-scoped knowledge access: ensuring each area of expertise only draws on the data relevant to it, so answers about one domain can't leak in data or assumptions from another.
- Bidirectional conversation flow: letting a caller change the subject mid-conversation and be handed to the right resource, without needing to hang up and start over.
- Graceful out-of-scope handling: recognizing when a question falls outside a given area of expertise and redirecting politely, rather than answering outside its remit or making something up.
- Voice-native interaction: supporting natural spoken language throughout, rather than rigid menus, keypresses, or exact-keyword triggers.

What This Project Solves

- Lets a PM or TPM ask about user feedback, support tickets, or product metrics in natural spoken language and be connected to whoever actually holds that data; without knowing in advance which dashboard or team owns the answer.
- Keeps each area of product-health data cleanly separated, so an answer about support tickets can't be contaminated with engagement-metrics assumptions, or vice versa.
- Supports natural topic-switching mid-call: a caller can move from asking about NPS to asking about churn risk without restarting the conversation.
- Declines and redirects gracefully when asked something outside the system's scope entirely, instead of guessing or fabricating an answer.
